Abstract. Brain tumors are highly aggressive tumors that are characterized by high levels of matrix metalloproteinase (MMP)-2 and -9 secretions that degrade the extracellular matrix (ECM) and basement membrane, allowing cancer cells to spread to distal organs. Proteases play a key role in tumor cell invasion and metastasis by digesting the basement membrane and ECM components. Strong clinical and experimental evidence demonstrates association of elevated levels of urokinase plasminogen activators (uPA) and MMPs with cancer progression, metastasis and shortened patient survival. MMP activities are regulated by specific tissue inhibitors of metalloproteinases (TIMPs). Our main objective was to study the effect of a nutrient mixture (NM) on the activity of uPA, MMPs and TIMPs in various human gliomas. Human glioblastoma (LN-18, T-98G and A-172) cell lines (ATCC) were cultured in their respective media and treated at confluence with NM at 0, 50, 100, 250, 500 and 1000 µg/ml. Analysis of uPA activity was carried out by fibrin zymography, MMPs by gelatinase zymography and TIMPs by reverse zymography. Glioblastoma cell lines LN-18 and T-98G expressed uPA, which was inhibited by NM in a dose-dependent manner. However, no bands corresponding to uPA were detected for the A-172 cell line. On gelatinase zymography, all three cell lines showed bands corresponding to MMP-2 and LN-18 and T-98G showed PMA (100 ng/ml)-induced MMP-9. NM inhibited their expression in a dose-dependent manner. Activity of TIMP-2 was upregulated by NM in all glioma cell lines in a dose-dependent manner. Analysis revealed a positive correlation between uPA and MMP-2 and a negative correlation between uPA/MMPs and TIMP-2. These findings suggest the therapeutic potential of NM in the treatment of gliomas.

Introduction

Approximately 23,130 new cases and 14,080 deaths from brain and nervous system tumors were estimated in the United States for adults in 2013 (1). Brain cancer (mainly gliomas and medulloblastomas) is the second (after leukemia) leading cause of cancer death in children aged under 15, accounting for one third of all cancer deaths in this age group (2). In 2013, approximately 4,300 children younger than the age of 20 were expected to be diagnosed with primary brain tumors, of whom 3,050 were under the age of 15 (2). Gliomas, a broad term which includes all tumors arising from the supportive tissue of the brain, represent 30% of all brain tumors and 80% of all malignant tumors (2). Glioblastomas represent 17% of all primary brain tumors and 54% of all gliomas (2). Some pediatric brain tumors, such as brain stem gliomas and pontine gliomas, are terminal upon diagnosis and no new protocols have been developed in 30 years (3). Though most brain tumors tend not to metastasize to distant areas outside the brain and/or spinal cord, they do tend to recur locally or spread to other areas of the CNS. Tumor cell invasion depends upon degradation of the extracellular matrix (ECM), which, when intact, acts as a barrier to block cancer cell invasion. The ECM is composed of collagen, proteoglycans, fibronectin, laminin and other glycoproteins (4-6). Two families of proteases, the matrix metalloproteinases (MMPs) and urokinase plasminogen activators (uPA) are involved in tumor invasion and metastasis. Numerous clinical and experimental studies have demonstrated that elevated levels of uPA and MMPs are associated with tumor growth, cancer progression, metastasis and shortened survival in patients (7). MMPs, especially MMP-2 and MMP-9 play key roles in tumor cell invasion and metastasis due to their ability to degrade type IV collagen, a major component of basement membranes (6,8,9). MMP-2 and -9 are secreted as inactive pro-enzymes in their latent zymogenic form, and activated by other MMPs or proteases. Proteolytic activities of MMP-2 and MMP-9 are inhibited by specific inhibitors, tissue inhibitors of metalloproteinases (TIMPs). Thus, a critical determinant of net proteolytic degradation is the balance between MMP and TIMP levels. Clinical studies note the association of MMP expression with progression of brain tumors (10,11). Jäälinoja et al found that MMP-2 expression correlated with survival in malignant brain tumors (10). The mean survival of patients with an MMP-2 negative tumor was 36 months, contrasted with 7-14 months.
in patients with an MMP-2 positive tumor (10). When Smith et al examined urine, cerebrospinal fluid and tissue specimens immunohistochemically from patients with brain tumors, they noted that brain tumor presence was significantly correlated with elevated MMP-2 and MMP-9 levels and resection of tumors correlated with decreased levels of MMPs (11).

The serine protease uPA converts plasminogen to plasmin, which is capable of promoting tumor growth and angiogenesis, degrading the ECM and basement membrane and activating pro-MMPs (12). Components of the uPA system such as uPA, plasminogen activator inhibitor-1 (PAI-1), and urokinase-type plasminogen activator receptor (u-PAR) are overexpressed in a variety of cancer types, most notably in breast cancer (13), but also in brain tumors (14), and correlate with cancer progression, metastasis and poor prognosis. Bindal et al reported that high levels of uPA were found in malignant glioma and metastatic tumors whereas normal levels of uPA were found in low-grade gliomas (14). Furthermore, patients with no detectable tissue plasminogen activator (tPA) activity correlated with histologically malignant brain tumors, aggressive characteristics and shorter survival (14). Thus the uPA system represents a potential target for anticancer strategies.

Rath and Pauling (15) proposed using nutrients such as lysine and ascorbic acid to target plasmin-mediated connective tissue degradation as a universal approach to tumor growth and expansion. Binding to plasminogen active sites, lysine blocks plasminogen activation into plasmin by tPA. Thus it modulates the plasmin-induced MMP activation cascade (16). Subsequent studies confirmed this approach and led to identifying a novel formulation composed of lysine, ascorbic acid, proline and green tea extract and other micronutrients (NM), which has shown significant anticancer activity against a large number (~40) of cancer cell lines, blocking cancer growth, tissue invasion and MMP expression both in vitro and in vivo (17). In this study, we focused on the modulating effect of NM on the activities of MMP-2 and -9, TIMPs and uPA in human glioblastoma cell lines LN-18, T98G and A-172.

Materials and methods

Materials. Human glioblastoma cell lines LN-18, T98G and A-172, along with their culture media were obtained from ATCC. Antibiotics, penicillin and fetal bovine serum (FBS), were obtained from Gibco (BRL, Long Island, NY). Twenty-four well tissue culture plates were obtained from Costar (Cambrdige, MA). Glatenase zymography was performed in 10% Novex pre-cast SDS polyacrylamide gel (Invitrogen Corp.) in the presence of 0.1% gelatin under non-reducing conditions. Culture media (20 µl) were mixed with sample buffer and loaded for SDS-PAGE with Tris glycine SDS buffer as suggested by the manufacturer (Novex). Samples were not boiled before electrophoresis. Following electrophoresis the gels were washed twice in 2.5% Triton X-100 for 30 min at room temperature to remove SDS. The gels were then incubated at 37°C overnight in substrate buffer containing 50 mM Tris-HCl and 10 mM CaCl₂ at pH 8.0 and stained with 0.5% Coomassie Brilliant Blue R250 and destained. Electrophoresis of uPA and tPA was conducted for comparison. Fibrin zymograms were scanned using CanoScan 9950F Canon Scanner.

Gelatinase zymography. Gelatinase zymography was performed in 10% Novex pre-cast SDS polyacrylamide gel (Invitrogen Corp.) in the presence of 0.1% gelatin under non-reducing conditions. Culture media (20 µl) were mixed with sample buffer and loaded for SDS-PAGE with Tris glycine SDS buffer as suggested by the manufacturer (Novex). Samples were not boiled before electrophoresis. Following electrophoresis the gels were washed twice in 2.5% Triton X-100 for 30 min at room temperature to remove SDS. The gels were then incubated at 37°C overnight in substrate buffer containing 50 mM Tris-HCl and 10 mM CaCl₂ at pH 8.0 and stained with 0.5% Coomassie blue R250 in 50% methanol and 10% glacial acetic acid for 30 min and destained. Upon renaturation of the enzyme, the gelatinases digest the gelatin in the gel and give clear bands against an intensely stained background. Protein standards were run concurrently and approximate molecular weights were determined by plotting the relative mobilities of known proteins.

Reverse zymography. TIMPs were analyzed by reverse zymography on 15% SDS-PAGE gels containing serum-free conditioned medium from cells. After electrophoresis the gels were washed twice with 2.5% Triton-X for 30 min at room temperature to remove SDS. The gels were then incubated at 37°C overnight in 50 mM Tris-HCl and 10 mM CaCl₂ at pH 7.6 and stained with 0.5% Coomassie blue R250, destained and scanned.

Scanning of gelatinase, reverse and fibrin zymograms. Gelatinase, reverse and fibrin zymograms were scanned using CanoScan 9950F Canon scanner at 300 dpi. The intensity of the bands was evaluated using the pixel-based densitometer.
program Un-Scan-It, Version 5.1, 32-bit, by Silk Scientific Corp. (P.O. Box 533, Orem, UT, USA), at a resolution of 1 Scanner Unit (1/100 of an inch for an image that was scanned at 100 dpi). The pixel densitometer calculates the optical density of each pixel (values 0-255) using the darkly stained background of the gel as a pixel value of 0. A logarithmic optical density scale was used since the optical density of the film and gels is logarithmically proportional to the concentration. The pixel densitometer sums the optical density of each pixel to give the band density.

**Statistical analysis.** Pearson’s correlation coefficient was determined between NM effect on the mean MMP-2, uPA and TIMP-2 expression of glioma cell lines using MedCalc Software (Mariakerke, Belgium).

**Results**

Table I provides an overview of the activity of uPA, MMP and TIMP-2 in the tested glioma cell lines.

**Effect of NM on uPA activity in human glioma cell lines.** Activity of uPA was detected in glioma LN-18 and T-98G cell lines. LN-18 and T-98G showed one band corresponding to subunit 1 at 55 kDa. However, no bands corresponding to uPA were detected for cell line A-172. NM exerted dose response inhibition with virtual block of uPA activity of subunit 1 in LN-18 at 250 µg/ml (linear trend R²=0.842) and in T-98G at 1000 µg/ml (linear trend R²=0.713). See Fig. 1 for respective fibrin zymograms and densitometry analyses.

**Effect of NM on MMP-2 and MMP-9 expression in the glioma cell line LN-18.** On gelatinase zymography, LN-18 cells demonstrated expression of MMP-2, but no MMP-9 expression. MMP-2 was inhibited by NM in a dose-dependent fashion with virtual total inhibition at 500 µg/ml (linear trend R²=0.677). PMA (100 ng/ml) treatment induced MMP-9 expression by LN-18 cells; NM inhibited MMP-2 and MMP-9 in a dose-dependent manner with total block of MMP-2 at 100 µg/ml (linear trend R²=0.734) and total block of MMP-9 at 50 µg/ml (linear trend R²=0.553). See Fig. 2 for gelatinase zymograms and densitometry analyses.

**Effect of NM on MMP-2 and MMP-9 expression in the glioma cell line T-98G.** On gelatinase zymography, T-98G cells demonstrated expression of MMP-2, but no MMP-9 expression. MMP-2 was inhibited by NM in a dose-dependent fashion with virtual total inhibition at 1000 µg/ml (linear trend R²=0.951). PMA (100 ng/ml) treatment induced MMP-9 expression by T-98G cells; NM inhibited MMP-2 and MMP-9 in a dose-dependent manner with total block of MMP-2 at 1000 µg/ml (linear trend R²=0.863) and total block of MMP-9 at 100 µg/ml (linear trend R²=0.734). See Fig. 3 for gelatinase zymograms and densitometry analyses.

**Effect of NM on MMP-2 and MMP-9 expression in the glioma cell line A-172.** On gelatinase zymography, A-172 cells demonstrated expression of MMP-2, but no MMP-9 expression even

Figure 1. Effect of NM on uPA activity in glioma LN-18 and T-98G cell lines. Fibrin zymograms of LN-18 (A) and T-98G (B) uPA expression. 1, uPA; 2, markers; 3, control; 4-8 NM, 50, 100, 250, 500 and 1000 µg/ml. Densitometric analyses of LN-18 (C) and T-98G (D) uPA expression.
with PMA (100 ng/ml) treatment. MMP-2 was inhibited by NM dose-dependently with virtual total inhibition at 1000 µg/ml (linear trend \(R^2=0.834\)). See Fig. 4 for gelatinase zymogram and densitometry analysis.
Effect of NM on TIMP activity in glioma cell lines. Reverse zymography revealed upregulation of TIMP-2 activity with NM treatment in all glioma cell lines in a dose-dependent manner. Minimum activity was expressed at 50 and maximum at 1000 µg/ml NM. See Fig. 5 for reverse zymograms and densitometry analyses.

Correlation between expression of uPA, TIMP-2 and MMP. Analysis revealed a positive correlation between expression of uPA and MMP-2 of NM-treated glioma cell lines LN-18 and T-98G, as shown in Table II. Fig. 6A shows the correlation graph for LN-18 uPA and MMP-2 with a correlation coefficient r=0.504. Negative correlations were found between the
expression of MMP-2 and TIMP-2 in all three glioma cell lines treated with NM as shown in Table II. The correlation (r=-0.842) between MMP-2 and TIMP-2 is shown for LN-18 in Fig. 6B. Negative correlations were found between expressions of TIMP-2 and uPA in glioma cell lines LN-18 and T-98G, as shown in Table II. Fig. 6C shows the correlation graph for LN-18 TIMP2 and uPA.

Discussion

Tumor cell invasion requires the critical steps of cell attachment, degradation of the ECM and migration through the disrupted matrix. The two families of proteases, matrix metalloproteinases and urokinase plasminogen activators play key roles in tumor cell invasion. Experimental studies have demonstrated the role of urokinase plasminogen, especially cell surface uPA, as an initiator of ECM proteolysis and associated tumor cell invasion (16). The protease uPA converts plasminogen to plasmin, which is capable of promoting tumor growth and angiogenesis, degrading the ECM and basement membrane and activating pro-MMPs (12). Overexpression of uPA in brain tumor patients has been correlated with cancer progression, metastasis and poor prognosis (14). Matrix metalloproteinases, especially MMP-2 and MMP-9, play pivotal roles in tumor cell invasion and metastasis due to their ability to degrade type IV collagen, a major component of basement membranes. Overproduction of MMPs, especially MMP-2 and -9 have been shown to be associated with a more aggressive behavior of brain tumors (10,11).

Our study demonstrated that the specific mixture of nutrients tested significantly inhibited uPA secretion in glioblastoma cell lines LN-18 and T-98G. (Glioma cell line A-172 was not found to secrete uPA in this study). Furthermore, the NM demonstrated dose-dependent decrease in MMP secretion and increase in TIMP-2 secretion by all glioma cell lines. As expected, a significant positive correlation was found between the secretion of uPA and MMP-2 and a significant negative correlation between uPA and TIMP-2 by NM treatment of glioma cell lines LN-18 and T-98G. In addition a significant negative correlation was found between MMP-2 and TIMP-2 secretion by NM treatment of all three glioma cell lines. Furthermore, a previous study demonstrated a significant negative correlation (r=-0.953) between NM inhibition of Matrigel invasion and NM modulation of the MMP-2 activity of glioma cell line A-172 (18).

In contrast to the associated toxicity and limited efficacy of standard cancer chemotherapy and radiation therapy, the efficacy and safety of dietary and botanical natural compounds in cancer prevention has been extensively documented (19). The nutrient mixture was formulated by selecting nutrients that act on critical physiological targets in cancer progression and metastasis, as documented in both clinical and experimental studies. Combining these micronutrients expands metabolic targets, maximizing biological impact with lower doses of components. A previous study of the comparative effects of NM, green tea extract and EGCG on inhibition of MMP-2 and MMP-9 secretion of different cancer cell lines with varying MMP secretion patterns, revealed the superior potency of NM over GTE and EGCG at equivalent doses (20). These results

can be understood from the more comprehensive treatment offered by the combination of nutrients in NM over individual components of NM since MMP-2 and MMP-9 are mediated by differential pathways.

Optimal ECM structure depends upon adequate supplies of ascorbic acid and the amino acids lysine and proline to ensure proper synthesis and hydroxylation of collagen fibers. In addition, lysine contributes to ECM stability as a natural inhibitor of plasmin-induced proteolysis (15,21). Manganese and copper are also essential for collagen formation. There is considerable documentation of the potency of green tea extract in modulating cancer cell growth, metastasis, angiogenesis and other aspects of cancer progression (22-28). N-acetyl cysteine and selenium have demonstrated inhibition of tumor cell MMP-9 and invasive activities, as well as migration of endothelial cells through ECM (29-31). Ascorbic acid demonstrates cytotoxic and antimitastatic actions on malignant cell lines (32-36) and cancer patients have been found to have low levels of ascorbic acid (37,38). Low levels of arginine, a precursor of nitric oxide (NO), can limit the production of NO, which has been shown to predominantly act as an inducer of apoptosis (39).

In conclusion, the NM demonstrated potent anticancer activity by targeting primary mechanisms responsible for the aggressive spread of gliomas. In this in vitro study, the NM significantly inhibited secretion of uPA and MMP-2 and -9, and increased secretion of TIMP-2 in glioma LN-18 and T-98 cells, suggesting its potential in modulating cancer invasion and metastasis. Glioma A-172 cells did not secrete uPA; however, MMP-2 secretion by A-172 was inhibited by NM and secretion of TIMP-2 was enhanced by NM. NM inhibition of MMP-2 secretion was found to be correlated significantly with Matrigel invasion of glioma A-172 cell line. Furthermore, use of the nutrient mixture would not pose any toxic effect clinically, especially in the relevant doses, as in vivo safety studies demonstrate. A previous in vivo toxicology study (Roomi et al., J Am Coll Nutr 22: 77, abs. 86, 2003) showed that NM had no adverse effects on vital organs (heart, liver and kidney), or on the associated functional serum enzymes.
