Received September 11, 2015; Accepted September 19, 2016

Abstract. Cigarette smoking has been shown to cause pathological alterations in the liver. However, how hepatic metabolism is altered during cigarette smoking-induced inflammation remains to be fully elucidated. In the present study, a rat model of smoking was established to examine the effects of cigarette smoking on inflammation, autophagy activity, and the expression of nuclear receptor and CYP in the liver. Elevated expression of interleukin 1β and activation of autophagy in the liver were observed upon smoking exposure in rats. Cigarette smoking induced a significant reduction in the mRNA expression levels of cytochromes, including cytochrome P450 (Cyp)1A2, Cyp2D4 and Cyp3A2. Accordingly, a decrease was also observed in glucocorticoid receptor (GR), a regulator of the expression of Cyp. Activation of the GR signal in human hepatic LO2 cells did not affect autophagic genes, however, it led to the upregulation of hCYP1A2, hCYP2C19 and hCYP3A4, and the downregulation of hCYP2C9. The GR antagonist, RU486, eliminated this effect, suggesting the importance of GR in liver metabolism upon cigarette smoking.

Introduction

Cigarette smoke contains >4,000 toxic chemicals with hazardous adverse effects on almost all organs in the body (1). The major clinical consequences of cigarette smoking include chronic respiratory ailments, increased incidence of several types of cancer and increased risk of cardiovascular disorders (2,3). In addition, smoking may accelerate the progression of fibrosis in patients with chronic renal or pancreatic diseases (4,5). Although not considered a causative agent, smoking may have a negative effect on the incidence, severity and clinical course of liver diseases, including primary biliary cirrhosis, chronic hepatitis C infection, nonalcoholic fatty liver disease and hepatocellular carcinoma (6-9). The mechanisms underlying smoking-induced liver alterations are complicated and remain to be fully elucidated.

The liver is the critical site in the body for the removal of toxins, and process alcohol and drugs. To perform these functions, the liver expresses heme-containing enzymes of the cytochrome P450 (CYP) families (10). In humans, the CYP1, CYP2 and CYP3 families are involved in hepatic drug metabolism. Other CYP families are involved in the biosynthesis and metabolism of steroids and retinoic acid. The CYP1 family has three members, CYP1A1, CYP1A2 and CYP1A3. CYP1A2 is expressed predominantly in the liver and is responsible for the metabolism of several drugs, including theophylline, which is used clinically to prevent and treat the wheezing, shortness of breath and chest tightness caused by asthma, chronic bronchitis, emphysema and other lung diseases (11). In the CYP2 family, the CYP2C subfamily constitutes ~20% of the total hepatic CYP and is involved in the metabolism of a wide variety of drugs in clinical use (12). Although CYP2D6 represents only 2% of the hepatic CYP content in humans, it metabolizes >70 drugs (11). Among the CYP3 family members, CYP3A4 is primarily expressed in the liver and catalyzes the metabolism of a number of drugs, for example statins, which are used to treat hyperlipidemia (13). The expression of CYP is considered...
to be controlled by nuclear factor (NF)-κB through nuclear receptors (14). Pregnane X receptor (PXR) can recognize and bind to the responsive elements in CYP2B and CYP2C genes (15). Constitutive androstane receptor (CAR), a nuclear receptor, has been shown to be involved in the regulation of CYP2C9 and CYP3A4 (16,17). Glucocorticoid responsive element has been identified in the regulatory region of the CYP2C9 promoter (18). The activation of glucocorticoid receptor (GR) is essential for the induction of CYP3A4 by glucocorticoids (19).

The activation of NF-κB is affected by pro-inflammatory cytokines, including interleukin 6 (IL6), interleukin 1 (IL1), and tumour necrosis factor α (TNFα), which are promoted by chemicals in cigarette smoke (20). The development of inflammation is regulated by autophagy through a chain of elements, including autophagy-related protein 5 (ATG5) and ATG12 (21,22). The in vitro treatment of liver cells with ethanol has been shown to increase the expression of IL6, an effect which was markedly alleviated by rapamycin, an inducer of autophagy (23). However, whether autophagic activity is altered in the liver of cigarette smokers remains to be elucidated.

In the present study, a rat model of smoking was established to examine the effects of cigarette smoking on inflammation, autophagic activity, and the expression of nuclear receptor and CYP in the liver. It was found that smoking induced a reduction in the expression of drug-metabolizing CYPs in the liver through the regulation of nuclear receptors. These findings indicate the importance of considering metabolic ability in the liver of patients who smoke prior to prescribing drugs.

Materials and methods

Ethics statement. The present study was performed in strict accordance with the recommendations in the Guide for the Care and Use of Laboratory Animals of Tianjin Medical University (Tianjin, China). The protocol was approved by the Animal Care Committee of Tianjin Medical University (Permit no. 2010-0002). All surgery was performed under sodium pentobarbital anesthesia, and all efforts were made to minimize suffering of animals.

Reagents. TR1zol reagent was purchased from Invitrogen; Thermo Fisher Scientific, Inc. (Waltham, MA, USA). The TIANScript RT kit was purchased from Tiangen Biotech Co., Ltd. (Beijing, China). SYBR Green polymerase chain reaction (PCR) core reagents were purchased from Bio-Rad Laboratories, Inc. (Hercules, CA, USA). RPMI 1640 medium was purchased from Gibco; Thermo Fisher Scientific, Inc. Fetal calf serum was purchased from Hyclone; GE Healthcare Life Sciences (Logan, UT, USA). Dexamethasone (Dex) was purchased from Sigma-Aldrich; Merck Millipore (Billerica, MA, USA). RU486 (mifepristone), a specific antagonist of glucocorticoid receptor, was purchased from Sigma-Aldrich; Merck Millipore.

Animals and treatment. Male Wistar rats weighing 180±20 g and aged 6 weeks were purchased from the Model Animal Center of the Radiological Medicine Research Institute, Chinese Academy of Medical Science (Beijing, China). The rats were housed in standard laboratory cages (n=5) at 22°C with a 12 h light/dark cycle and free access to food and water. A total of 30 rats were divided into two groups (15 per group), comprising a cigarette smoking-exposed group and an unexposed control group. As described previously (24), the smoking group received whole-body exposure to the smoke of five unfiltered cigarettes (Daqianmen™, tar ≤15 mg, nicotine ≤1.1 mg and CO ≤13 mg) for 30 min, twice daily (prior to 9:00 a.m and after 5:00 p.m), for 14 weeks inside a 0.6 m³ custom plexiglass chamber (constructed in-house). The protocol for the control group was identical, but without smoke exposure.

Cell culture. LO2 cells (a gift from Chenghu Liu lab, NanKai University, Tianjin, China) were maintained in RPMI 1640 medium supplemented with 10% fetal calf serum, 2 mM l-glutamine, 100 U/ml penicillin and 100 µg/ml streptomycin at 37°C with 5% CO₂. In the experiments, 10 nM Dex and 10 µM RU486 were added into the culture medium when the cells were 80% confluence.

Liver tissue sampling. At the end of smoking exposure period, the rats were anesthetized with sodium pentobarbital and sacrificed by cervical dislocation. The abdominal cavity was opened and the liver tissues were excised, rinsed in ice-cold PBS (pH 7.4), and then either stored at -80°C for the analysis of gene expression or fixed in 10% neutral-buffered formalin for the analysis of histology.

Hematoxylin and eosin (HE) staining. Following fixation in 10% neutral-buffered formalin, the liver tissues were embedded in paraffin and 5 µm thick sections were cut. The sections were then stained with HE solution (Solarbio Science & Technology Co., Ltd., Beijing, China) and images of the staining were captured under an Olympus IX71 microscope with a DP80 camera (Olympus Corporation, Tokyo, Japan).

Total RNA isolation and reverse transcription-quantitative PCR (RT-qPCR) analysis. RNA was extracted from either the liver tissues or the LO2 cells using TR1zol reagent. The RNA (3 µg) was then reverse transcribed using oligo (dT) primers for 1 h at 50°C using the TIANScript RT kit (Tiangen Biotech, Co., Ltd.) according to the manufacturer's protocol. The qPCR analysis was performed using the SYBR Green method. Specific gene primers were designed using PrimerQuest SM software (http://www.idtdna.com/Scitoools/Applications/PrimerQuest; Integrated DNA Technologies, Inc., Coralville, IA, USA), and then commercially produced (BGI Tech, Shenzhen, China; listed in Tables I and II). The DNA amplification reactions were performed on a Light Cycler 96 real-time PCR system (Roche Diagnostics, Indianapolis, IN, USA) under the following reaction conditions: An initial heating cycle of 95°C for 2 min; and 40 cycles alternating between denaturation at 95°C for 25 sec, primer annealing at 60°C for 25 sec and extension at 72°C for 20 sec. Melting curves were used to clarify the identity of amplicons, and the housekeeping gene, GADPH, served as an internal control. The relative mRNA expression levels of targeted genes were calculated using the
comparative Cq (quantification cycle) method normalized to GAPDH mRNA in the same sample. Briefly, specific ΔCq was calculated as follows: ΔCq = (Cq_{GAPDH}) - (Cq_{target}); and relative expression was defined as: $2^{-\Delta Cq}$ (24).

**Statistical analysis.** The data were analyzed using SPSS software, version 13.0 (SPSS, Inc., Chicago, IL, USA). Data from three or more independent experiments were collected and analyzed as the mean ± standard error of the mean. The significance of the results was assessed using a paired t-test between two groups. $P<0.05$ was considered to indicate a statistically significant difference.

**Results**

*Smoke exposure results in the upregulation of IL1β.* Evidence has been accumulating, which indicates that the progression of liver disease is associated with cigarette smoking (25). To assess the inflammatory status in the liver upon smoking exposure, the present study used a smoking-exposed rat model. Examination of liver tissues by HE staining showed no significant structural alterations or inflammatory infiltrates in the rats exposed to smoke for 14 weeks (smoke group), compared with the control group (Fig. 1A and B). However, the mRNA expression of IL1β was higher in the livers from the smoke

mTOR, mammalian target of rapamycin; ULK1, unc-51-like autophagy activating kinase 1; ATG, autophagy-related protein; LC3, microtubule-associated protein 1 light chain 3; CYP, cytochrome P450.

Inflammation is shown to involve cross-talk with autophagy in the liver (23). To evaluate the effects of smoking on autophagic activity in the liver, RT-qPCR analysis was performed. The results revealed that the expression of mammalian target of rapamycin (mTOR), an inhibitor of autophagy, was decreased in the smoke group, compared with the control group, although this was not significant (data not shown). However, the expression of AMP-activated protein kinase (Ampk), a negative regulator of the mTOR pathway, was elevated when the rats were exposed to smoke (Fig. 2A). In addition, the expression of Wip1, a positive regulator of the mTOR pathway, was decreased in the smoke group, compared with the control group (Fig. 2B). These findings indicated that autophagy in the liver may be induced by smoking. To confirm this, the present study examined the effects of smoking on the expression of autophagy-associated genes in the liver tissues. The expression levels of Atg5 and Atg12 were comparable between the smoke group and control group (Fig. 2C and D). However, the expression levels of Ulk1 and annexin A3 (Anx3), a homolog of human microtubule associated protein 1 light chain 3 (LC3) were significantly higher in the smoke group, compared with those in the control group (Fig. 2E and F). Taken together, these data suggested that autophagy was upregulated in the liver upon smoking exposure.

Smoking induces a reduction in the expression of rat hepatic Cyp genes. Cyp enzymes possess the capacity to catalyze the oxidative biotransformation of the majority of drugs. To examine whether smoking-induced inflammation alters hepatic function by regulating the expression of Cyp, the present study measured the expression of Cyp genes in the liver. A significant reduction in the mRNA expression level of Cyp1A2 was observed in the smoke group, compared with the control group (Fig. 3A). For the Cyp2 family, the expression of Cyp2D4, but not Cyp2C9 or Cyp2C19, was significantly reduced following smoke exposure (Fig. 3B-D). As for the Cyp3 family, the expression of Cyp3A2 was decreased in the smoke group (Fig. 3E). In concordance with previous reports showing a reduction in the expression of Cyp during inflammation (26,27), these data suggested that smoking-induced inflammation altered the catalyzing capacity of the liver.
It is known that the gene expression of Cyp is regulated by nuclear receptors, including PXR and CAR (28-30). The present study investigated effects of smoking exposure on the expression of these nuclear receptors in the liver. It was found that the hepatic mRNA expression of CAR was comparable between the control and smoke groups (Fig. 4A). However, the expression levels of PXR and GR were significantly reduced in the smoke group, compared with the control group (Fig. 4B and C). These results suggested that the reduction in the hepatic expression of Cyp in the smoking-exposed rats may have been attributed to the reduced synthesis of nuclear receptors, including GR, in the liver.

Figure 1. Liver pathology in cigarette smoke-exposed rats. Hematoxylin and eosin staining of liver tissues (magnification, x100) harvested from (A) unexposed rats (Control) and (B) cigarette smoke-exposed rats (Smoke). mRNA expression levels of (C) IL1β, (D) IL6 and (E) TNFα were determined in the control group and smoke group using reverse transcription-quantitative polymerase chain reaction analysis with Gapdh as the housekeeping gene. Data are presented as the mean ± standard error of the mean (*P<0.05, compared with the control group). IL, interleukin; TNFα, tumor necrosis factor α.

Figure 2. Smoke exposure increases autophagy in the liver. mRNA expression levels of the autophagy regulators, (A) Ampk and (B) Wip1, and autophagy-associated components, including (C) Atg5, (D) Atg12, (E) Ulk1 and (F) Anx3, were measured in the liver using reverse transcription-quantitative polymerase chain reaction analysis. Gapdh was used as the housekeeping gene. Data, obtained from 10 rats per group, are presented as the mean ± standard error of the mean. *P<0.05 and **P<0.01, compared with the control group. Ampk, AMP-activated protein kinase; Wip1, wild-type p53-induced phosphatase 1; Atg, autophagy-related protein; Ulk1, unc-51-like autophagy activating kinase 1; Anx3, annexin A3.
GR mediates the expression of CYP in human hepatocytes. The present study used the LO2 human hepatocyte cell line to evaluate the role of GR in regulating the expression of CYP. The LO2 cells were treated with Dex alone or with Dex and the GR inhibitor, RU486 for 2 days. LO2 cells are sensitive to Dex. Compared with the control cells (Fig. 5A), treatment with Dex alone resulted in morphological alterations, for example the LO2 cells became longer and more stretched (Fig. 5B). These morphological changes were absent when the LO2 cells were treated with Dex and RU486 (Fig. 5C). The expression of CYP3A4 was increased by Dex treatment, while the expression of CYP2C9 was decreased by Dex treatment (Fig. 5D). The expression of CYP2C19 was increased by Dex treatment, but the increase was reduced by RU486 (Fig. 5E). By contrast, treatment with Dex alone resulted in a significant reduction in the expression of CYP2C9 in LO2 cells (Fig. 5F). The expression of CYP2C9 in the Dex and RU486 group returned to a level, which was comparable with that of the control cells. However, Dex had no effect on the expression of CYP2D6 (Fig. 5G). Similar to CYP3A4, LO2 cells with Dex alone led to an increase in the expression of CYP2C19, although not significantly, in cells treated with Dex and RU486, compared with the Dex group (Fig. 5E). By contrast, treatment with Dex alone resulted in a significant reduction in the expression of CYP2C9 in LO2 cells (Fig. 5F). The expression of CYP2C9 in the Dex and RU486 group returned to a level, which was comparable with that of the control cells. However, Dex had no effect on the expression of CYP2D6 (Fig. 5G). Similar to CYP3A4, LO2 cells with Dex alone led to an increase in the expression of CYP2C19, although not significantly, in cells treated with Dex and RU486, compared with the Dex group (Fig. 5E). By contrast, treatment with Dex alone resulted in a significant reduction in the expression of CYP2C9 in LO2 cells (Fig. 5F). The expression of CYP2C9 in the Dex and RU486 group returned to a level, which was comparable with that of the control cells. However, Dex had no effect on the expression of CYP2D6 (Fig. 5G). Similar to CYP3A4, LO2 cells with Dex alone led to an increase in the expression of CYP2C19, although not significantly, in cells treated with Dex and RU486, compared with the Dex group (Fig. 5E). By contrast, treatment with Dex alone resulted in a significant reduction in the expression of CYP2C9 in LO2 cells (Fig. 5F). The expression of CYP2C9 in the Dex and RU486 group returned to a level, which was comparable with that of the control cells. However, Dex had no effect on the expression of CYP2D6 (Fig. 5G). Similar to CYP3A4, LO2 cells with Dex alone led to an increase in the expression of CYP2C19, although not significantly, in cells treated with Dex and RU486, compared with the Dex group (Fig. 5E). By contrast, treatment with Dex alone resulted in a significant reduction in the expression of CYP2C9 in LO2 cells (Fig. 5F). The expression of CYP2C9 in the Dex and RU486 group returned to a level, which was comparable with that of the control cells. However, Dex had no effect on the expression of CYP2D6 (Fig. 5G). Similar to CYP3A4, LO2 cells with Dex alone led to an increase in the expression of CYP2C19, although not significantly, in cells treated with Dex and RU486, compared with the Dex group (Fig. 5E). By contrast, treatment with Dex alone resulted in a significant reduction in the expression of CYP2C9 in LO2 cells (Fig. 5F). The expression of CYP2C9 in the Dex and RU486 group returned to a level, which was comparable with that of the control cells. However, Dex had no effect on the expression of CYP2D6 (Fig. 5G). Similar to CYP3A4, LO2 cells with Dex alone led to an increase in the expression of CYP2C19, although not significantly, in cells treated with Dex and RU486, compared with the Dex group (Fig. 5E). By contrast, treatment with Dex alone resulted in a significant reduction in the expression of CYP2C9 in LO2 cells (Fig. 5F).
RNA expression levels of mTOR, ATG5, ATG12, LC3 or ULK1 were found in the Dex-treated cells, compared with the control cells or the Dex and RU486-treated cells (Fig. 6A–E). Among the genes selected in the present study, only the expression of Beclin 1 was reduced in the Dex-treated cells, however, the addition of RU486 did not recover the expression level (Fig. 6F). Taken together, these data suggested that GR had minimal effect on the regulation of autophagy in LO2 cells.

Discussion

Cigarette smoking is considered to be a major preventable contributor to morbidity and mortality rates worldwide. In addition to the lungs, the liver is also affected by chemicals produced from cigarettes, either directly or indirectly. In the present study, a reduction in the expression levels of CYPs were observed in the livers from cigarette smoking-exposed rats. The data also suggested that autophagy was activated on exposure to cigarette smoking. Using human liver LO2 cells, it was shown that GR, at least in part, mediated the smoking-induced alteration in the expression of CYPs.

CYPs constitute the major enzyme family capable of catalyzing the oxidative biotransformation of the majority of drugs, and are, therefore, of particular relevance for clinical pharmacology (31,32). Among these enzymes, the CYP1, CYP2 and CYP3 families are responsible for metabolizing the majority of drugs (33). Theophylline represents a routine drug used to treat wheezing, shortness of breath and chest tightness, which are normally observed in patients with chronic bronchitis or emphysema (11). The chemicals derived from cigarette smoke affect the lung predominantly by triggering...
airway inflammatory responses, resulting in the development of emphysema and respiratory bronchiolitis (34). In the present study, it was found that the hepatic expression of Cyp1A2, which metabolizes theophylline, was reduced in the smoking-exposed rats. Hussain et al (35) reported that incense smoke induces the expression of CYP1A2 (35). This discrepancy may be associated with the severity of injury induced by the smoke. However, when theophylline is used to treat patients with chronic bronchitis or emphysema, its efficacy and retention may be altered in patients who smoke. Notably, a significant reduction was also observed in the expression of members of the CYP2 and CYP3 families. Therefore, smoking cessation may be considered to provide optimal treatment for patients who smoke.

It is known that CYPs are predominantly generated in hepatocytes, the damage of which can affect the quantities and qualities of CYPs. The severity of liver injury correlates positively with levels of inflammation (36). Hepatic inflammation is prompted by the binding of cyclic pro-inflammatory factors to toll-like receptor 4 in hepatic Kupffer cells. The activated Kupffer cells initiate the secretion of inflammatory cytokines, which in turn activate NF-kB (37). The nuclear-translocated NF-kB forms a complex with GR, prevents the binding of GR to GR-responsive elements, and inhibits the transcription of PXR and CAR (38,39). The reduction in the levels of PXR and CAR, which bind to the responsive elements of DNA, results in the inhibition of CYP3A transcription and a subsequent decrease in its expression (40-42). The role of GR in the regulation of CYPs has been a matter of debate. Experiments using rats have supported the involvement of this nuclear receptor in the regulation of CYPs. The present study found that GR was decreased in the livers of rats exposed to smoke. Using LO2 human liver cells, the present study showed that the activation of GR with Dex upregulated the expression of CYP1A2, CYP2C9 and CYP3A4, but downregulated the expression of CYP2C9. The effect was reversed when the LO2 cells were treated with the Dex and GR inhibitor, RU486. These data, together with previous findings (43), demonstrated that the GR signal exhibits a differential role in regulating the hepatic expression of CYPs.

Autophagy, a cellular self-protective process predominantly involving the recycling of its own nonessential organelles to maintain homeostasis, can be activated by certain stimuli (44). In the present study, it was observed that autophagy was upregulated in the livers of rats upon smoking exposure. However, smoking-induced autophagy in the liver was independent of the GR signal. In certain cases, autophagy or autophagy-associated proteins may induce apoptosis or necrosis, and autophagy has been shown to degrade the cytoplasm excessively, leading to autophagic cell death (45). Therefore, whether or not autophagy is involved in hepatic metabolism through regulating the expression of CYPs requires investigation addressed in the future.

In conclusion, the present study demonstrated an association between cigarette smoking and metabolic alterations in the liver by investigating the expression of CYP genes at the transcriptional level. Future investigations on protein expression levels are required to confirm these preliminary findings. Experiments can be designed to treat emphysema in rats with anti-inflammatory drugs. The hepatic metabolism of such drugs may be evaluated and compared between smoking and control groups. Another smoking cessation group can be included to
evaluate the contribution of smoking cessation to the hepatic metabolism of drugs. These investigations are likely to provide clues to improve treatment in patients who smoke.
